

Using Containers on HPC resources

Charles Peterson

April 20, 2022

Overview

Welcome!

In this workshop, we will go over using containers on HPC resources, like UCLA's Hoffman2

- We will go over basic container concepts
- Also, some basic examples of using containers on HPC resources
- Look more more advance container building in a future workshop!!

Any suggestions for
upcoming workshops,
email me at
cpeterson@oarc.ucla.edu

Files for this Presentation

This presentation can be found on github under `container_04_18_2022` folder

https://github.com/ucla/hpc_workshops

The `sIides` folder has this slides.

- PDF format: [ContainerWS.pdf](#)
- html format: [html](#) directory

Note: This presentation was build with Quarto/Rstudio.

- Quarto file: [ContainerWS.qmd](#)

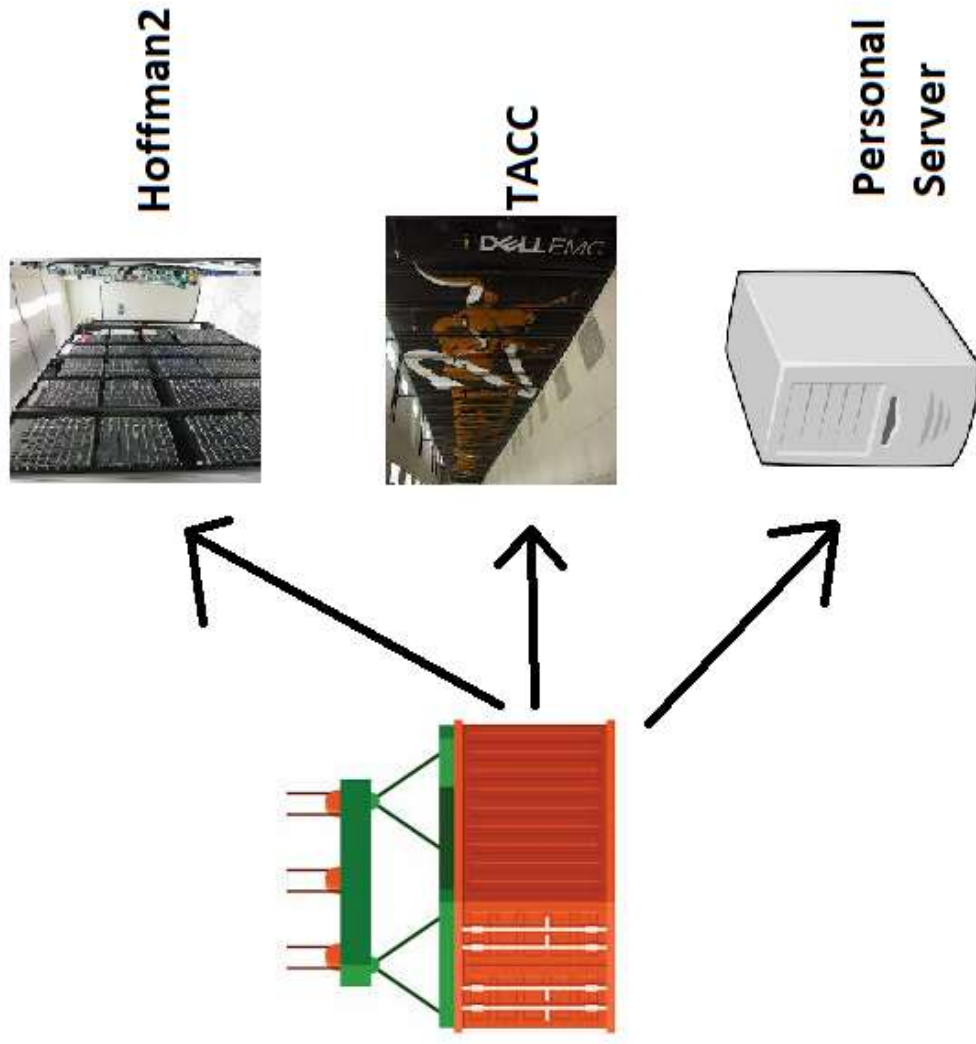

What are Containers?

What are Containers?

What are Containers?

Virtualization

To understand how Containers work, we will have a brief overview on Virtualization

Bare computer setup

- Typical setup in which your software applications run directly on the OS from the **physical** hardware
- Many HPC users run their applications in this fashion

Virtualization

Virtual Machine setup

- Applications running inside of a VM are running on a completely different set of (virtual) resources
 - Example: VirtualBox, VMWare, AWS EC2
- A “Machine” within a “Machine”

Virtualization

Container Setup

- Applications running inside of a container are running with the **SAME** kernel and physical resources as the host OS
- A “OS” within a “OS”

Why use Conatiners?

- Bring your own OS
- Portability
- Reproducibility
- Design your own environment
- Version control

Problems installing apps

- Researchers typically have to spend lots of time installing software in their personal (HOME) directories, load modules, every time software is used
- Then start all over when using software on a different HPC resource

HPC resources (like Hoffman2) are
SHARED resources

- Researchers are running software on the same computing resource
- No 'sudo' and limited yum/apt-get commands available

Container Advantages

- Install your application once
 - Use on any HPC resource
- A 'virtual' OS
 - users can have complete OS admin control

- Great to easily install software with apt/yum
- Great if you software requires MANY dependencies that would be complex installing on Hoffman2.

- Easily share containers!!
 - containers as a .SIF file
 - save to a Cloud Container Registry
 - DockerHub, GitHub packages, Nvidia NGC

FreeStyle
Docker
QemuZ
Kubernetes
AWS-ECS
Podman
Singularity
CoreOS
Mesos
Virtuoso
chroot
XCC
Scherie
Vagrant
Saltstack
VBoxer
Packer
Kubelet
Fargate
EC2

- One of the most popular containerize software
- Many popular cloud container registries to store Docker containers

- # Podman

- Similar syntax as with Docker
- Doesn't have a root daemon process
- On some HPC resources (not on Hoffman2, yet)

Apptainer

• Formerly Singularity

- Designed and developed for HPC systems

- Mostly likely installed on HPC systems (installed on Hoffman2)

- Supports Infiniband, GPUs, MPI, and other devices on the Host

- Can run Docker containers

Security

- considerations

- Built with shared user system environments in mind
- NO daemon run by root
- NO privilege escalation. Cannot gain control over host/Hoffman2
- All permission restrictions outside of the a container apply to the inside

Apptainer workflow

Create

Transfer

Run

Apptainer workflow (Create)

Create

- Build a container by installing

Transfer

Apptainer on your computer

Run

(where you have root/sudo

access) to create a container

- Use a pre-built container
 - Search Container Registries for container
 - DockerHub, GitHub packages, Nvidia NGC

Apptainer workflow (Transfer)

Create

Bring your container to Hoffman2

Transfer

- Copy your container to Hoffman2

Run

```
scp test.sif H2USERNAME@hoffman2.idre.ucla.edu
```

- Pull a container from online Container Register

```
apptainer pull docker://ubuntu:20.04
```

- Use a container pre-built on Hoffman2

```
#Pre-built container location on Hoffman2  
ls $H2_CONTAINER_LOC
```

Apptainer workflow (Run)

Create

Run Apptainer on your container

Transfer

Can run in an interactive (qysh)

Run

session

```
qysh -l h_data=5G  
module load apptainer/1.0.0  
apptainer exec mypython.sif python3 test.py
```

Or run as a Batch (qsub) job

```
cat << EOF >> myjob.job  
module load apptainer/1.0.0  
apptainer exec mypython.sif python3 test.py  
EOF
```

```
qsub -l h_data=5G myjob.job
```

Apptainer container run like any other application

Common Usage

On Hoffman2, to use apptainer, all you need to do is load the module

```
module load apptainer/1.0.0
```

- Only module you need to load!
 - Expect MPI module if running parallel

Common Apptainer commands:

- Getting a container from somewhere

```
apptainer pull [options]  
apptainer pull docker://ubuntu:20.04
```

- Build a container

```
apptainer build [options]  
apptainer build myapp.sif myapp.def
```

Common Usage

Common Apptainer commands:

- Run a command within a container

```
apptainer exec [options]  
apptainer exec mypython.sif python3 test.py  
# Runs the command `python3 test.py` inside the container
```

- Start an interactive session inside your container

```
apptainer shell [options]  
apptainer shell mypython.sif
```

NOTE: Apptainer will NOT run on Hoffman2 login nodes.

Examples

- Example 1: Simple container jobs
- Example 2: Using GPUs
- Example 3: Using MPI
- Example 4: Simple custom build container

Example 1: TensorFlow

- Go to [EX1](#) directory
- Look at [tf-example.py](#)

To run this job, we will run

```
python3 tf-example.py
```

Need tensorflow!!:

- Instead of installing it yourself, let's find a container

Visit [DockerHub](#)

Example 1: TensorFlow (interactive)

Running on Hoffman2

- Start an interactive session

```
qssh -l h_data=10G
```

- load the apptainer module

```
module load apptainer/1.0.0
```

- pull the TensorFlow container from DockerHub

```
apptainer pull docker://tensorflow/tensorflow:2.7.1
```

- We see a SIF file named, tensorflow_2.7.1.sif
- Start an interactive shell **INSIDE** the container

```
apptainer shell tensorflow_2.7.1.sif  
python3 tf-example.py
```

Example 1: TensorFlow (batch)

Run a command inside the container

```
qrun -l h_data=10G
module load apptainer/1.0.0
apptainer pull docker://tensorflow/tensorflow:2.7.1
apptainer exec tensorflow_2.7.1.sif python3 tf-example.py
```

Alternatively, you can submit this as a batch job

- Example job script: [tf-example.job](#)

```
qsub tf-example.job
```

NOTE:

- See that we didn't need to load any python module!
- We didn't need to install any TF packages!!

Example 2: GPU containers

Look under [EX2](#)

This example will use Pytorch with GPU compute nodes

- File: `pytorch_gpu.py`

Let us go to [Nvidia GPU Cloud \(NGC\)](#)

- Containers built by Nvidia
- Optimized for GPU jobs

Example 2: GPU job

First, you will need a GPU compute node

```
qcrsh -l h_data=10G,gpu
```

Download PyTorch from Nvidia NGC

```
module load apptainer/1.0.0  
apptainer pull docker://nvcv.io/nvidia/pytorch:22.03-py3
```

Run apptainer with the **--nv** option. This option will find the GPU drivers from Host compute node

- See if container can find the GPUs

```
apptainer shell pytorch_22.03-py3
```

```
apptainer exec --nv tensorflow_2.7.1.sif python3 tf-example.py
```

Alternatively, you can submit this as a batch job

Example 3: Parallel MPI containers

This example will run a parallel MPI container with NWChem

Many applications use MPI to run over many CPUs.

One of my fav Computational Chemistry application is NWChem

On Hoffman2, we have already built a NWChem container with MPI

`$H2_CONTAINER_LOC/h2_nwchem:7.0.2.sif`

Run the Parallel NWChem job

```
qsub nwchem-MPI.job
```

Example 3: Parallel MPI containers

NOTE: Typically, you will run MPI application by following the format

```
mpirun myapp.x
```

Inside the container, you have mpirun before the **apptainer** command

```
mpirun apptainer exec myapp.sif myapp.x
```

Example 4: Building container

I have a chemistry code I built on github

- <https://github.com/charliecpeterson/QUILL>

We need:

- Python with the PySCF package
- Eigen3

Instead of installing these dependencies on H2 (or looking for modules), lets build a container!!

Build using three methods

- Writable sandbox
- Using a definition file (.def)
- Using Docker (Dockerfile)

Example 4

For this example, you will need Apptainer and/or Docker installed on a machine that you have admin/sudo access.

In order to build or modify containers, you must have admin access

- So you cannot do this on Hoffman2

You may use [wscontainers.ova](#) VM to use with VirtualBox. Both Apptainer and Docker pre-installed.

- Username & password : wscontainer

Example 4: Method 1 - Writable Sandbox

This example will create a container by installing software inside of a container interactively

- Create a writable container, starting from base ubuntu image

```
sudo aptainer build --sandbox quill.sif docker://ubuntu:20.04
```

- Go inside writable container (Modification are saved)

```
sudo aptainer shell --writable quill.sif
```

Example 4: Method 1 - Writable Sandbox

- Install QUILL

```
apt-get update
DEBIAN_FRONTEND=noninteractive apt-get install -y --no-install-recommends \
    git python3 python3-dev python3-pip \
    libeigen3-dev ca-certificates cmake make gcc g++
rm -rf /var/lib/apt/lists/*

pip3 install pyscf
ln -s /usr/bin/python3 /usr/bin/python
mkdir -pv /apps
cd /apps
git clone https://github.com/charliecpeterson/QUILL
cd QUILL
mkdir build ; cd build
cmake .
exit
```

Move final container to Hoffman2

```
scp QUILL.sif H2USERNAME@hoffman2.idre.ucla.edu
```

Example 4: Method 2: Definition file

Install QUILL with a Definition file

Look at `quill.def`

This file has all steps needed to build the QUILL container.

```
sudo aptainer build quill.sif quill.def
```

The `quill.sif` container is created

Move container to Hoffman2

```
scp QUILL.sif H2USERNAME@hoffman2.idre.ucla.edu
```

Example 4: Method 3: Docker

You can use Docker to create containers for apptainer

The [Dockerfile-quill](#) file is used by Docker to create the container

```
sudo docker build . -t quill:1.0 -f Dockerfile-quill
```

See built docker container

```
sudo docker image list
```

Save docker image to apptainer container

```
sudo docker save quill:1.0 > quill.tar  
apptainer build QUILL.sif docker-archive://quill.tar  
scp QUILL.sif H2USERNAME@hoffman2.idre.ucla.edu
```

Alternatively, you can [docker push](#) your container to DockerHub, GitHub, etc and run [docker pull](#) on

Example 4: Running Container

Once the container is on Hoffman2, submit job.

```
qsub quill.job
```

Things to Think About

Size of container

More Things to Think About

- Share .sif files with your friends!
 - Save your (Docker) containers to DockerHub or GitHub Packages
- Find examples of Dockerfiles and Apptainer def files on my GitHub
 - <https://github.com/charliepeterson/containers>
- Experiment creating your containers with writable sandboxes, then create Def/Dockerfile to with all your commands so to rebuild/modify containers later
- Look out for a follow-up workshop
 - Container Building

Thank you!
